

I5020 Computer Security

Quizz 4: Malware and protection

This assessment evaluates the following competencies:

- CS201 Understand software protections that can be installed on a computer system
- CS206 Explain techniques that can be used to protect a system against malware

Three affirmations are given for each assessed competency. For each of them, you have to decide whether it is true or false. To get a star for the competency, you must have the correct answer for the three affirmations.

An anti-malware system can become the source of a DoS attack on the system. It is possible to use encryption techniques to detect if a file has been corrupted and therefore probably infected by a virus or any other malware. It is possible to monitor the system calls to detect some kinds of viruses or other malwares. CS206 Network communications sniffing can help detecting malware, namely by identifying signatures of their operations. A technique to prevent malware is to block some operations on a host and ask the user if he/she is the initiator or these "critical" operations. Checking the values of each pixel of the screen to detect patterns revealing the operations of a malware is a relevant and efficient malware detection technique.	ho CS201	True	False
